STATE OF CONNECTICUT

REVISED AGE AND SEX DISTRIBUTIONS OF POPULATION PROJECTIONS FOR CONNECTICUT MUNICIPALITIES & REGIONS TO THE YEAR 2000

DECEMBER 1984

CONNECTICUT OFFICE OF POLICY & MANAGEMENT
COMPREHENSIVE PLANNING DIVISION
80 WASHINGTON STREET
HARTFORD, CT 06106

STATE OF CONNECTICUT

OFFICE OF POLICY AND MANAGEMENT

December, 1984

TO: Users of Population Projections for the State of Connecticut and Connecticut Municipalities

FROM: Anthony V. Milano, Secretary

SUBJECT: Revised Age and Sex Distributions of Population Projections for Connecticut Municipalities and Regions to the Year 2000 -- December 1984

Forwarded are the revised age and sex distributions of population projections for Connecticut. This report contains revisions to the age and sex distributions promulgated in June 1983. These population projections with age and sex distributions are forwarded for use in plans and activities involving all state programs. The methodology for the preparation of the age and sex distributions of the population projections is contained in this report.

The total populations projected for each municipality, region and the State have not been changed from the projections published by this agency in June of 1982. The revisions in this report contain changes only in the distribution of persons by age and sex within those previously determined population totals.

These age and sex distributions should be utilized by agencies of the State of Connecticut in their planning and policy activities. Specific inquiries concerning these population projections or their use may be addressed directly to Gary E. King, Under Secretary, Comprehensive Planning Division, of the Office of Policy and Management. Staff may be contacted at 566-8286.

We express our appreciation to the Department of Health Services which provided both information and assistance in the preparation of this report. Computer software development and data processing services were provided by the Institute for Social Inquiry, University of Connecticut.

We believe these age and sex distributions of the population projections represent the best current determination of future population distributions of State of Connecticut, its regions and municipalities.

REVISED AGE AND SEX DISTRIBUTIONS OF POPULATION PROJECTIONS FOR CONNECTICUT REGIONS AND MUNICIPALITIES TO THE YEAR 2000

DECEMBER 1984

Connecticut Office of Policy and Management
Comprehensive Planning Division
80 Washington Street
Hartford, CT 06106

ACKNOWLEDGEMENTS

The age and sex distributions presented in this report were revised under the direction of Gary E. King, Under Secretary, Comprehensive Planning Division, Horace H. Brown, Director, and Theron A. Schnure, Assistant Director. Maria A. Buatti, Planning Analyst II was responsible for project coordination and data analysis. Sterling E. Green, Jr., Manager of User Services at the Institute for Social Inquiry, University of Connecticut, developed the computer software.

ADDITIONAL INFORMATION SOURCES

Additional copies of this report are available for $7.00 plus tax, postage and handling. The age and sex distributions and the area aggregations printed in this report are also available on machine-readable tape. Users may phone the Connecticut Census Data Center Center with inquiries regarding price and tape copying specifications.

The fertility and mortality rates utilized in the preparation of the revised age and sex distributions are available in a separate listing, available upon request from the Connecticut Census Data Center. Based upon empirical data obtained from the Vital Registry, Connecticut Department of Health Services, the rates are presented in the following format: average fertility and mortality rates for the period 1978-1982 for 5 year age cohorts for each sex and each municipality.

Persons with inquiries regarding the revised age and sex distributions may call Maria Buatti at the Connecticut Census Data Center, (203) 566-8286. The mailing address is: Comprehensive Planning Division, Connecticut Office Of Policy and Management, 80 Washington Street, Hartford, CT 06106.

First Printing: December, 1984

INTRODUCTION

This report presents revised distributions of the projected resident population of each Connecticut municipality by 5 year age and sex groups for the projection years 1985, 1990, 1995 and 2000. Also presented are summary aggregations of the municipality projections for the following areas within Connecticut: regional planning areas, health service areas, counties, and the State.

The age and sex distributions presented in this report have been revised from similar distributions published by this office in July, 1983. Only the distributions of persons by age and sex within the total population have changed; the population projection totals for each municipality are the same as those published in the 1983 report. Following is a brief history of the development of the projections and the age and sex distributions.

In February 1980 the Connecticut Office of Policy and Management (OPM) published total population projections for the State's 169 municipalities for intervals of five years for the period 1980-2000. In June 1982 OPM presented modified projections in a report titled Population Projections for Connecticut Municipalities and Regions to the Year 2000. In this report the projected population totals for each municipality were adjusted, both to maintain the slow, steady growth assumption from the 1980 projection series and to incorporate the 1980 census population counts as a new base.

In July 1983 the 1982 population projections were disaggregated into five year age and sex cohorts. While maintaining the previous projection totals for each municipality as a population control, projections were developed to distribute persons by age and sex within those totals. These distributions were contained in the report titled Age and Sex Distributions of Population Projections for Connecticut Municipalities and Regions to the Year 2000.

The revisions to the July 1983 distribution series presented in this report contain new distributions of the population by age and sex within the previously established population projection totals for each municipality. The revisions are the result of methodological changes, while the basic demographic assumptions were generally not changed.

The age and sex distributions of the population projections presented in this report reflect the future course of Connecticut's population given the following assumptions:

- The total population of the State will increase over the next twenty years, with a slow and steady growth of about 2.2% every five years. The net growth of 8.8% statewide will not be evenly distributed across the state, but will tend to be concentrated in the suburbs of our major cities and regionally in the Housatonic Valley and Midstate Planning Regions.

- Mortality and fertility in each municipality will remain constant over the twenty year projection period at the average rates for the period 1978-1982.

METHODOLOGY

Population projections are, by definition, the quantitative outcome of a mathematical procedure which simulates, using a computer model, the effect of certain assumptions about the future characteristics of a population. The age and sex distributions in this report were developed using a demographic model, where the assumptions quantitatively described the three major components of population change: fertitlity, mortality and migration. The assumptions were applied using a cohort component survival method combined with a procedure of prorated adjustmentsswith cross-iteration.

The process began with 1980 census counts of persons by age and sex for each Connecticut municipality. The single year age counts were collapsed into five year age groups, or cohorts, for each sex. The youngest cohort was the group aged 0-4 years and the eldest was the group aged 85 years or older. The yield was 36 individual 5 year cohorts covering both sexes. Together these cohorts formed the base distribution for the projection of the population by age and sex.

The model mathematically applied the assumptions about future change to this base population for each municipality. Each assumption, expressed as a rate of change, was intended to describe the anticipated changes within a specific period of time called the projection period. Because five year cohorts were used to group the population counts, the projection periods were also five years in length. The projections in this report cover four projection periods, beginning in 1980-85 and extending to the period 1995-2000.

The process of projecting is to theoretically "survive" a population to the end of the projection period by applying the assumptions about future change to the base distribution. The outcome of the process is a new, or projected population distribution five years later.

FERTITITY ASSUMPTION:

- Fertility will remain constant at rates for 1980 for each municipality over the next twenty years.

The assumption expressed stabilized rates as a function of average annual births for the period 1978-1982 over the 1980 census counts of females between the ages of 10 and 49 years. The annual general fertility rate for the State was 42.01 births per 1000 women aged 10-49 years. The assumption's annual total fertility rate for Connecticut was 303.61 births per 1000 women

aged 10-49 years. The assumption's crude fertility rate for the State was 12.56 births annually per 1000 persons.

The average number of births during the period 1978-82 for each 5 year age cohort of females between the ages 10-49 years by municipality of residence was obtained from the registered birth certificates in the Connecticut Vital Registry, Department of Health Services.

For each of the four projection periods and for each municipality the constant, age-specific year birth rates were applied to a mid-point population of females between the ages of 10-49 years. The mid-point populations were developed with an adjustment of each female age cohort by subtracting expected deaths over the projection period to estimate each cohort's size in the next projection year. A linear interpolation between the cohorts in the base year and the cohorts in the projection year yielded the mid-point cohort population of women of child-bearing age for the middle year of the projection period.

The application of age-specific birth rates to each mid-point female population yielded expected births for one year for each municipality. Total annual births for each municipality were obtained by summing the births for all cohorts of females of childbearing age. Each single-year total cohort of newborns was multiplied by 5 to form the base for the new cohort aged 0-4 years in the projection year. The total births for the projection period were then sub-divided into male and female newborn cohorts using the 1980 census count ratio of males to females under 1 year of age.

MORTALITY ASSUMPTION:

- Mortality, and therefore survival, will remain constant at rates for 1980 for each municipality over the next twenty years.

The assumption expressed stabilized mortality rates for each municipality and for each sex and 5 year age cohort as a function of average annual deaths for the period 1978-82 over the respective 1980 census counts for each cohort.

The annual crude death rate of the assumption for the State was 8.51 deaths per 1000 persons per year. Within each municipality and for the State as a whole, the rates increased with cohort age for both sexes. Rates for males were higher at all ages.

The average number of deaths to Connecticut residents during the period 1978-1982 by 5 year age group by municipality of residence was obtained from the registered death certificates in the Connecticut Vital Registry, Department of Health Services.

For each municipality the constant, age-specific death rates were applied to their respective base population cohorts. Deaths for each cohort

were multiplied by five to yield the expected total deaths for a cohort over the 5 year projection period. Total cohort deaths were subtracted from the respective base cohorts to arrive at the surviving persons, now five years older, in the projection year.

The model essentially "aged" the population in order to determine potential survivors of expected mortality experience over the projection period. For each municipality, beginning with the newly determined births for each sex, and on through each age cohort to the most elderly group (age 85+ years), each base population cohort was multiplied by its unique death rate. The resulting cohorts, having theoretically "survived" the projection period, were considered to be 5 years older. This resulting distribution formed the foundation of the newly projected population of each municipality.

INSTITUTIONAL POPULATION ASSUMPTION:

- Certain, pre-determined census tracts containing institutional populations within municipalities throughout the state will maintain relatively constant, unique age and sex distributions of the population over the twenty year projection period.

It was assumed that the population of census tracts containing large institutions would remain relatively constant over the entire projection period. These tracts, with large facilities such as children's homes, colleges or universities, or hospitals and housing for the elderly, could not be projected using standard fertility and mortality/survival techniques.

Since specific age and sex distributions of persons within each institution were not available from the 1980 census, distributions for the respective census tract areas containing each identified institution were used. In order to prevent theoretical aging of the identified institutional populations, the age and sex distributions for each of these tracts were held constant for each projection period. By subtracting the tract populations of each age and sex cohort from each municipality distribution before determining births, and adding the tract populations back in to their original cohorts after the survival process, the original institutional age distributions of the tracts were generally preserved.

Thirty-nine census tracts in 21 Connecticut municipalities were identified as containing institutional populations which required this method. Listing 1 on pages 11-13 presents tract and municipality coding and the 1980 census population counts for each tract and its group quarters.

MIGRATION ASSUMPTION:

- An age-specific migration assumption had been included in the population projections used as controls, and

therefore was not directly included in the methodology for determining the revised age and sex distributions in this report.

A specific migration figure for each municipality had been directly included in the development of the OPM 1980 population projection series, and was retained in the 1982 adjusted series. In each of these projection series a 2.2% average net growth statewide which included both migration and the natural increases resulting from births and deaths was shown for each projection period.

Migration data for persons by age, sex and municipality were not available for either the 1983 age and sex distributions or for the revisions presented in this report. Instead, the original (OPM 1980, 1982) growth rate was maintained by holding constant the projected population totals for each municipality and adjusting the survived population distributions to the control totals.

ADJUSTMENTS TO CONTROLS:

As a result of the above procedures a new distribution of population for each municipality for the projection year had now been developed which reflected changes due to natural increase (births and deaths) in each age group over the five year projection period. These distributions were then adjusted further to reflect the overall population growth inherent in the population projection control totals for each municipality.

For each projection year the municipality projection control totals were first subdivided by sex, again using the 1980 ratios of males to females. (The assumption that the ratio of males to females will remain constant was developed after reviewing census data over the past 40 years for a sample of municipalities.) The resulting sub-divided populations of males and females became the projection controls for each municipality.

The newly developed age and sex distributions for each municipality were then summed, and the resulting total projected distributions were compared to their respective male and female controls. The differences were considered to be a balance population (or the residual population) for the projection period. This balance population could not be termed residual net migration because the fertility and mortality assumptions used to develop the controls were not the same as those used to develop the distributions. Therefore the balance population for each municipality could be attributed only in part to migration.

For each municipality, the balance populations for males and females were then redistributed back over their respective age and sex distributions by allocating to each cohort a proportional share of the balance. This procedure resulted in the largest cohorts (also those which were the fastest growing) receiving the largest share of the balance population. Similarly,

the smallest cohorts (always the group aged 85+ years) received the smallest share, and grew at the slowest rate.

The sum of the projected age distributions now equaled the previously projected population controls for both males and females. Had it not been for one outstanding consideration, a complete series of age and sex population distributions for all municipalities for a single projection year would now have been complete. Because of an anomaly in the derivation of survival rates from the mortality data, one further adjustment procedure was necessary.

The mortality assumption intended that each municipality would experience constant mortality rates for each age and sex cohort over the entire projection period. In order to accurately capture the intended mortality experience unique rates for each municipality were used. This allowed the preservation of the historical age and sex distribution of the population in each municipality.

The use of local mortality rates did not, however, contain the accurate probabilities that each cohort would survive the projection period at historical rates. Probabilities which closely approximate survival experience of an age and sex cohort are only available through the use of a life table, a theoretical construct based upon the historical death statistics of a large population (at least 100,000 persons). Only five of the State's municipalities has a population of that magnitude, and it was not feasible to develop and examine the effects of regional life tables for this project.

From the perspective of total population the numerical differences are almost insignificant between a population survived using age-specific mortality rates and and one survived using life table based survival probabilities . Yet important differences occur within the population in the distribution of persons by age. These differences are concentrated in the youngest and oldest age cohorts, or the "tails" of the population distribution. A life table, which generates survival probabilities based upon interrelated experiences of all cohorts, yields survival rates for the tail cohorts which are higher than mortality based survival rates.

The unique population distributions for each municipality could only be preserved using historical mortality data, yet accurate cohort size for the tails could only be achieved through the use of a statewide life table. A method was chosen which incorporated the best characteristics of both approaches by yielding both local specificity and accurate projections for the newborn and very elderly populations.

Statewide controls for each projection year were necessary and were constructed, using the "1980 Connecticut Abridged Life Tables" developed by the CT Department of Health Services, Division of Health Statistics. The base population distributions for males and females for the State of Connecticut were survived independently, using average statewide fertility rates and the survival rates from the 1980 Connecticut Life Tables.

The total survived populations for both males and females were

adjusted proportionally to meet the total projected population of the State. These individual age and sex cohorts for the State served as the statewide controls for each projection year.

For each municipality the newly projected age and sex distributions were first adjusted, across all age cohorts, to meet their respective statewide age cohort. For each sex all of the cohorts for a given age group were summed across all 169 municipalities. This total was compared to its respective statewide cohort, the statewide control developed using the life table. The difference, or balance population for that age cohort, was proportionally reapplied back to the individual cohorts in each municipality. Because the differences in survived cohort size between the municipality cohorts and the statewide control cohorts were concentrated in the tails, this adjustment procedure did not significantly alter the cohorts in the middle of the age distributions. The adjustments instead corrected the tail cohorts to reflect a more accurate survivor population for each municipality.

For each sex, the age cohorts were then summed and the newly adjusted totals for each municipality were again compared to their respective municipal projection controls for the projection year. The differences were proportionally reapplied back to the age and sex distributions in order to complete one full cycle of prorated adjustments with cross-iteration.

Four full cycles of this procedure were necessary to smooth the distributions of each municipality to the established tolerance level. At the completion of each full cycle the balance populations for both the municipal and statewide adjustments were within -.999 and +1.001 persons.

Having utilized the prorated adjustments with cross-iteration procedure, the outcome was a matrix for both males and females which contained the age distributions for each municipality for the projection year. When summed for each municipality, the total of the cohorts equaled the municipal projection control for the projection year. When summed for each age cohort, across all municipalities, the total also equaled the statewide control for that age and sex cohort.

The age and sex distributions for a projection year were then complete and constituted the base population distribution used to project forward to the next projection year.

The entire process described above was repeated for each new projection year by applying the same assumptions of fertility and mortality to the new base and adjusting to the already existing controls. The process was repeated 4 times to develop age and sex distributions for municipalities for the each of the 5 year projection periods from 1980 to 2000.

In order to produce tables describing distributions of persons, it was necessary to round each cohort to a whole number. The rounding process unavoidably altered the precision of the balanced statewide matrix and accounts for the minor differences noted in the municipal and regional control totals.

RESULTS

Upon completion the municipal distributions were aggregated to display the age and sex distributions for larger areas. Aggregations are presented in this report for the State and for planning regions, health service areas, and counties. The Statewide aggregations represent both the statewide controls and the sum of the component cohorts from each municipality.

A comparative review of the statewide population in the revised age and sex distributions shows some differences from the distributions published in 1983.

The revision methodology produced a slight decline of 9,035 persons in the cohort 65 years and older by the year 2000 when compared to the 1983 distributions. While the entire elderly population is now smaller at the end of the twenty year projection period, the oldest cohort, those 85 years and older, is significantly larger. This is due to the revision methodology's increased probabilities for survival, which were concentrated in the tails of the population age distributions. These probabilities shifted the gain in life expectancy towards the most elderly, or 85+, cohorts. The greatest change in the revisions is the proportional size of the 85+ cohort which now almost doubles between 1980 and 2000 to become 1.5% of the year 2000 population.

Overall, the elderly population, aged 65 years and older, continues to show the most pronounced proportional growth over the twenty year projection period. From 364,864 persons in 1980, or 11.7% of the population, this group grows steadily to 516,002 or 15.3% of the population in the year 2000, an increase of 151,138 persons.

The revised distributions also show the cohort 0-4 years growing by almost 15,000 children from 1980 to peak at 200,032 in 1990. This cohort then declines to 183,037 in the year 2000 for a net change over the twenty year period of -1.2%. In 1980 the cohort 0-4 years was 5.96% of total State population. In 1990 the group will grow to 6.14% and then decline to become 5.41% of total State population in the year 2000.

In the revised age and sex distributions the youth population (combined cohorts aged 0-19 years) will decrease by 150,000 persons over the next twenty years from 30.1% of the total 1980 population to 23.3% in the year 2000. As the female "baby boom" population (those persons born during the approximate period 1945-1965) ages past the child-bearing years, the number of children born in each projection period will decline, even under the assumption of constant fertility rates and increased newborn survival.

The combined cohorts aged 20-64 years may be termed the mature population and broadly described as the employed or supporting population. This is the largest population age group in the State, numbering 2,171,964 persons in 1980. This age group will show only slight proportional increases over the entire projection period, growing from 58.2% of the population in

1980 to 61.5% in the year 2000. This minor growth represents approximately 270,000 persons.

With life expectancy now longer than ever before in history, expected deaths over the twenty year projection period will not significantly decrease the size of the baby boom population. Even with fewer young persons entering the 20-64 years age group over a twenty year period, the large population at the older end of the age range will hold the broad age ranged mature population relatively constant. Therefore, there will be no dramatic shifts over the next twenty years from demographic variables in the mature population because the baby boom cohorts will still remain within the age range of 20-64 years.

The revisions show a diminished size in the age cohorts between 10-29 years when compared to the 1983 age and sex distributions. The previous distributions contained occasional inflated cohorts in this age range which could not be understood after an examination of both the assumption rates and the methodology. The revised methodology has leveled the artificial peaks previously seen in this age group.

Because the revisions now show smaller cohorts aged 10-29 (which also contain fewer potential mothers), there are fewer total births in each municipality in each subsequent projection year. However, the population cohorts of surviving children (0-4 years) in the revisons are not significantly lower than the youngest cohorts in the 1983 age and sex distributions. This is due to the methodological changes for both the calculation of births on the midpoint populations and the procedure of prorated adjustments with cross-iteration which adjusted the youngest and eldest populations to the higher life table survival probabilities. The revisions show that statewide, in each projection period, fewer potential mothers will produce fewer newborns, but the number of children surviving their first five years will be greater.

A graphic display of the revised aged and sex distributions for 10 year cohorts over the twenty year projection period may be seen in Chart 1, "PROJECTED POPULATION OF CONNECTICUT BY AGE: 1980-2000," on the following page.
